

Explainable AI for Science

Shilpika¹, Carlo Graziani¹, Coletton Grossman¹, Mihai Anitescu¹²,
Bethany Lusch¹, Venkatram Vishwanath¹, Michael E. Papka¹

Argonne National Laboratory, The University of Chicago

Introduction: Model Interpretability

“Explainable AI (XAI)” founded by DARPA

- **Transparency:** Shows the internal logic of the model or explains outputs in an interpretable way.
- **Interpretability:** Makes it easier for humans to understand the *meaning* of a model’s predictions.
- **Justification:** Provides human-readable reasoning behind decisions.
- **Traceability:** Allows tracking the data and processing steps that led to a decision.

Local vs. global explanations

Model-agnostic vs. Model-specific

Explanation coverage = region in input space where the
explanation applies

Model-Agnosticism And Statistical Learning

Key Idea: Adopt a view of AI that abstracts away the model

Focus not on what the model *is*, but rather on what it *does*.

All statistical learning features a *training stage* and an *inference stage*

Training:

- Take a set of data, and infer an approximation to the statistical distribution from which the data was sampled;
 - “Data” could be images, weather states, protein structures, text...
- Simultaneously, optimize some decision-choosing rule in a space of such decisions, exploiting the learned distribution;
 - “Decision” could be the forecast of a temperature, or a label assignment to a picture, or the next move of a robot in a biochemistry lab, or a policy, or a response to a text prompt...

Inference:

When presented with a new set of data samples,

- produce the decisions appropriate to each one, using facts about the data distribution and about the decision optimality criteria inferred in training.

This view of AI encourages a model-agnostic outlook, which emphasizes data distributional structure and decision-space optimality, and diverts attention away from model computational structure.

Probabilistic Attribution Score: AS

$$A_{\mu} \equiv \log \frac{\Pr(\mathbf{R}|\mathbf{P})}{\Pr(\mathbf{R}|\mathbf{P} - P_{\mu})},$$

The basic idea is that if we have a prompt $\mathbf{P}$ that induces a response $\mathbf{R}$ sampled from the distribution $\Pr(\mathbf{R}|\mathbf{P})$ (where $\mathbf{P}$ and $\mathbf{R}$ are token sequences), then we would like a measure of attribution of the importance to the μ -th prompt token P_{μ} to $\mathbf{R}$.

Probabilistic Attribution Score: AS

$$A_{\mu} \equiv \log \frac{\Pr(\mathbf{R}|\mathbf{P})}{\Pr(\mathbf{R}|\mathbf{P} - P_{\mu})},$$

$$\begin{aligned} \Pr([L_{\mu}, \dots, L_{\mu+\nu}] | [L_1, \dots, L_{\mu-1}]) &= \Pr(L_{\mu} | [L_1, \dots, L_{\mu-1}]) \\ &\quad \times \Pr(L_{\mu+1} | [L_1, \dots, L_{\mu}]) \times \dots \\ &\quad \dots \times \Pr(L_{\mu+\nu} | [L_1, \dots, L_{\mu+\nu-1}]). \end{aligned}$$

The basic idea is that if we have a prompt $\mathbf{P}$ that induces a response $\mathbf{R}$ sampled from the distribution $\mathbf{P}(\mathbf{R}|\mathbf{P})$ (where $\mathbf{P}$ and $\mathbf{R}$ are token sequences), then we would like a measure of attribution of the importance to the μ -th prompt token P_{μ} to $\mathbf{R}$.

Probabilistic Attribution Score: AS

$$A_{\mu} \equiv \log \frac{\Pr(\mathbf{R}|\mathbf{P})}{\Pr(\mathbf{R}|\mathbf{P} - P_{\mu})},$$

$$\begin{aligned} D &\equiv \Pr(\{\mathbf{R} = \mathbf{r}\} | \{\mathbf{P} - P_{\mu} = \mathbf{p} - p_{\mu}\}) \\ &= \Pr(\{\mathbf{R} = \mathbf{r}\} | \{\mathbf{P}^{<\mu} = \mathbf{p}^{<\mu}\} \cap \{\mathbf{P}^{>\mu} = \mathbf{p}^{>\mu}\}) \end{aligned}$$

The basic idea is that if we have a prompt $\mathbf{P}$ that induces a response $\mathbf{R}$ sampled from the distribution $\mathbf{P}(\mathbf{R}|\mathbf{P})$ (where $\mathbf{P}$ and $\mathbf{R}$ are token sequences), then we would like a measure of attribution of the importance to the μ -th prompt token P_{μ} to $\mathbf{R}$.

D is the denominator of A_{μ} .

OLMO-2-0425-1B-INSTRUCT Response: 1997." is the answer. Yes / no, based on this passage. The passage is

Contextual Entropy vs AS - Greedy

- Contextual Entropy: Entropy of the distribution of each token conditioned on the rest of the context: with or without the response context.
- Low contextual entropy means that given the context ($\circ$ or $\times$) the model prefers fewer replacement tokens for the given token.
- High contextual entropy corresponds to more uncertainty in potential token replacements candidates.

Contextual Entropy with Prompt and Prompt + Response Context

- Token: Police
- Contextual entropy is higher at near-zero AS.
- KL Divergence is low = 0.0075.
- Greedy sampling

Prompt: The **police** officer walked into the room, carefully examining every clue. The information was sparse, but he believed the clues would lead him to the truth. He looked at the doorknob, noticing something odd about it. He made a note to check it more

Response: closely.

He walked over to the door and examined the doorknob more closely. It was a...

Model Language as a Testbed for Large Language Models

- Gaussian mixture of dialects such that we sample a dialect with weights, w , and then sample from the corresponding dialect matrix (also multivariate) and adding together the vectors.
- We set it so that 10% of the tokens differ between the common language and selected dialect.
- We tokenize along the real number line with bounds set to the bounds of our Gaussian mixture of dialects.
- Thus, we can calculate the next token probabilities of our model language.

BERT Capacity for Learning Model Language

- We use a mini-BERT with 6 hidden layers and 128 hidden size.
- We plot BERT next-token probabilities compared to model next token probabilities and show it learns the distribution further as training vectors n increase.

Hypothesis for Weight Shifting

A model fine-tuned on a single dialect must be a convex linear combination of a pre-trained model and a model fine-tuned only on that single dialect.

- $cP(t_n|T_{<n}, M_P) + (1 - c)P(t_n|T_{<N}, M_S) = P(t_n|T, M_F)$
- Rearranging to regress for c using OLS we have,
- So, $\hat{c} = \frac{\sum_n (P_P - P_S)(P_F - P_S)}{\sum_n (P_P - P_S)^2}$
- P = pretrained, F = finetuned, S = trained on a single dialect

Null Prompting

- Null prompted Llama 3-8B model 100,000 times
- Prompted Llama 3-8B model with prompt “medicine” 100,000 times
- Response length set to 128 tokens
- Had Claude classify the responses according to the Library of Congress classification system :
 - class(First Letter – “Q” = Science)
 - subclass(Second letter – “QA” = Mathematics)
 - subcategory(number range – QA76.75 = Computer Software)

Shifting of Weight

We essentially have a picture of what distribution that Claude is sampling from in its responses based on its classifications and see a shift in weights.

Shift within Subclass

- Shifts within each subclass
- Not just shift in class sampling
- This graph shows how much of these big subclasses made up the overall class distributions and the shift between them

Shift within Subclass

Top-5 subcategories within each of the 10 biggest subclasses (Null vs Medicine)

We also see significant subcategory shift within each subclass between the prompts

Shifting of Weight – Base and Fine-Tuned

Shifting of Weight – Prompt Length

We essentially have a picture of what distribution that Claude is sampling from in its responses based on its classifications and see a shift in weights

Conclusion

- Model-agnostic explanations
- Test how well an LLM converges to the underlying distribution of the training data
- Non-parametric linking first principles of probability theory to token attribution
- Can be used to test other XAI method, since sensitivity is inherently build-in the attribution method
- Compare different LLM models
- Reinforcement learning and its effects on the entropy of the model responses and catastrophic forgetting
